Seahorses are currently facing great challenges in the wild, including habitat degradation and overexploitation, and how they will endure additional stress from rapid climate change has yet to be determined. Unlike most fishes, the poor swimming skills of seahorses, along with the ecological and biological constraints of their unique lifestyle, place great weight on their physiological ability to cope with climate changes. In the present study, we evaluate the effects of ocean warming (+4°C) and acidification ($\Delta\text{pH} = -0.5$ units) on the physiological and behavioural ecology of adult temperate seahorses, *Hippocampus guttulatus*. Adult seahorses were found to be relatively well prepared to face future changes in ocean temperature, but not the combined effect of warming and acidification. Seahorse metabolism increased normally with warming, and behavioural and feeding responses were not significantly affected. However, during hypercapnia the seahorses exhibited signs of lethargy (i.e. reduced activity levels) combined with a reduction of feeding and ventilation rates. Nonetheless, metabolic rates were not significantly affected. Future ocean changes, particularly ocean acidification, may further threaten seahorse conservation, turning these charismatic fishes into important flagship species for global climate change issues.

Key words: Acidification, behaviour, *Hippocampus guttulatus*, metabolism, ocean warming, seahorse

Introduction

Seahorses are charismatic fishes that catch people's attention with their unusual beauty and unique lifestyle. They are admired and sought all around the world, with millions of seahorses being traded every year for traditional medicine, aquarium and curio trade (Lourie *et al.*, 2004). In recent decades, however, these fishes started to draw attention for the wrong reasons. Many seahorse species are currently threatened worldwide by

intensive exploitation and overfishing, as well as by the widespread degradation of their natural habitats. Seahorses were included both in the IUCN Red List of Threatened Species and in the Appendix II of CITES, as well as in some regional and national lists of threatened species (Vincent *et al.*, 2011).

The unique life-history features of seahorses make them particularly sensitive to overfishing and disturbance of their natural environment and, thus, an important and pressing

focus for global conservation efforts (Vincent *et al.*, 2011). Given the poor swimming skills and small home ranges of these fishes, migration to more suitable areas is somewhat restricted. Moreover, their camouflage defence strategy and sparse distribution associated with structurally complex habitats implies that not all habitats are equally suitable for them. Additionally, mate fidelity and the formation of pair bonds (which allows them to increase reproductive efficiency) means that when pair bonds are broken the seahorses may have trouble finding a new partner owing to their low population densities and sparse distribution; even when partners are replaced, their reproductive output may be affected. Reproductive rates of seahorses are already limited by the low fecundity, small brood size and lengthy parental care of these fish. Besides, male pregnancy implies that the survival of the young inside the brood pouch depends on the survival of the male (Foster and Vincent, 2004). Given the vulnerability of seahorses and the current concerns regarding their conservation, the question that arises is how will these already-threatened fish endure additional stress from rapid climate change?

The climate is changing at an unprecedented rate. Carbon dioxide (CO₂) has greatly increased in the atmosphere, from pre-industrial levels of 280 ppm to present-day levels of 379 ppm, and is expected to continue rising up to 730–1020 ppm by the end of the century. The oceans act as carbon sinks, sequestering CO₂ from the atmosphere. As a result, the continuous CO₂ uptake by the oceans is projected to lead to a drop of 0.3–0.4 units in ocean pH by the year 2100. At the same time, the atmospheric temperature is rising due to increasing concentrations of greenhouse gases produced by human activities and is estimated to increase by a further 1.1–6.4°C by the end of the century. Consequently, the oceans are absorbing some of this heat from the atmosphere and becoming warmer (Meehl *et al.*, 2007).

These expected environmental changes are predicted to have profound impacts on marine organisms and may trigger cascading effects on population, community and ecosystem dynamics (e.g. Pörtner *et al.*, 2004, 2005; Fabry *et al.*, 2008). Ocean warming will elicit thermal stress for a wide range of coastal marine organisms as their thermal limits are approached or even exceeded (Hofmann and Todgham, 2010). Beyond a certain thermal threshold, biological processes, such as metabolism, growth, feeding, reproduction and behaviour, may be negatively affected, compromising the overall fitness and survival of the species (e.g. Roessig *et al.*, 2004; Hoegh-Guldberg *et al.*, 2007; Byrne, 2011). Moreover, marine organisms at higher temperatures are likely to be more vulnerable to other environmental stressors, such as ocean acidification (e.g. Metzger *et al.*, 2007; Rosa and Seibel, 2008; Rosa *et al.*, 2014). Increased CO₂ levels may be responsible for reduced calcification rates and dissolution of calcareous structures in calcifying organisms (Hofmann *et al.*, 2010) and may also affect the survival, growth, development, behaviour, digestion and respiratory physiology of marine species (e.g. Rosa and Seibel, 2008; Munday *et al.*, 2009, 2011; Stumpff *et al.*, 2012, 2013; Jutfelt *et al.*, 2013).

In this study, we evaluate the effects of ocean warming (+4°C) and acidification ($\Delta\text{pH} = -0.5$ unit) on the metabolism, ventilation rate, feed intake and behavioural patterns of adult temperate seahorses, *Hippocampus guttulatus*, in order to understand how these fish will respond to future changes in ocean temperature and chemistry. *Hippocampus guttulatus* is one of the two seahorse species that inhabit European waters and, like other seahorses, is currently facing great conservation concerns (Faleiro, 2011; Caldwell and Vincent, 2012).

Materials and methods

Specimen collection and stocking conditions

Adult seahorses, *H. guttulatus*, were collected using SCUBA diving equipment near Caldeira de Tróia, a shallow water habitat near the inlet of the Sado estuary (38°29'18.42" N; 8°53'15.12" W), on the west coast of Portugal.

Seahorses (ranging between 4 and 15 g) were acclimated for 1 month to different temperature and pH combinations. Temperature scenarios were chosen to reflect the following conditions: (i) the average annual temperature (18°C); (ii) the average temperature during summer heat waves (26°C); and (iii) the expected warming scenario (+4°C) for summer heat waves (30°C). All temperature scenarios were tested in conditions of normocapnia [0.04% CO₂, partial pressure of CO₂ ($p\text{CO}_2$) = ~400 μatm] and hypercapnia (0.14% CO₂, $p\text{CO}_2$ = ~1400 μatm , $\Delta\text{pH} = -0.5$ units), making a total of six experimental treatments.

Seahorses were kept in recirculating systems (three systems per treatment). In each system, one non-pregnant male and one female were individually incubated at a density of one seahorse per 38.3 litres, making a total of six seahorses per treatment. Systems were filled with filtered (1 μm) and ultraviolet (UV)-irradiated seawater (salinity 35) and illuminated with a photoperiod of 14 h light–10 h dark. Water quality was ensured using protein skimmers, bioballs and UV sterilizers. Concentrations of ammonia, nitrites and nitrates were monitored regularly and kept within recommended levels. Water changes of 20% were performed daily to maintain total alkalinity and dissolved inorganic carbon speciation due to bacterial activity. Seahorse husbandry conditions were defined based on previous studies with this species (see Faleiro *et al.*, 2008; Planas *et al.*, 2008). Plastic plants were provided as holdfasts. All fishes were wet-weighted and identified with coloured-bead necklaces loosely held around the neck with an elastic cotton string. Seahorses were fed *ad libitum* twice a day with frozen enriched adult *Artemia* and *Mysis*.

Water temperature and pH were monitored via a Profilux system connected to individual temperature and pH probes. Temperature was automatically upregulated by heaters and downregulated using chillers. The pH was adjusted automatically via solenoid valves; it was reduced by injection of a certified

CO₂ gas mixture or upregulated by aerating the tanks with CO₂-filtered air. Additionally, seawater temperature and pH were manually monitored daily using a multiparameter portable meter, in order to cross-calibrate the temperature and pH probes and to adjust the set points of the systems as required. Seawater carbonate system speciation (see [Supplementary Table S1](#)) was calculated weekly from total alkalinity (see [Sarazin *et al.*, 1999](#)) and pH measurements. Bicarbonate and *p*CO₂ values were calculated using the CO2SYS software, with dissociation constants from [Mehrbach *et al.* \(1973\)](#) as refitted by [Dickson and Millero \(1987\)](#).

After 1 month of acclimation, the metabolism, ventilation rates, feed intake and behavioural patterns of adult seahorses were analysed under the different climate change scenarios. At the end of the experiments, tags were removed and all seahorses were released into their original habitat without injuries.

Metabolic rates, thermal sensitivity and ventilation rates

Oxygen consumption rates (OCRs) of adult seahorses were determined as an estimate of routine metabolic rates, after a starvation period of ~24 h. Seahorses were individually placed within an intermittent flow-through respirometry set-up (Loligo Systems), filled with filtered (0.2 µm) and UV-irradiated seawater to avoid bacterial contamination. Holdfasts were provided for seahorse attachment. The water was pumped at a constant flow rate (average 140 ml min⁻¹) through the respirometry chambers (550 ml vertical acrylic cylinders). During measurements of oxygen consumption, the flow was interrupted so that the system could operate like a closed respirometry set-up. Oxygen concentrations were recorded at the entrance and exit of each respirometer chamber with Clark-type O₂ electrodes connected to a Strathkelvin Instruments 929 oxygen interface. Measurements were performed in temperature-controlled conditions using a Lauda water bath. Before and after each run, the experimental set-up was calibrated and checked for electrode drift and microbial oxygen consumption. Each experiment was 6 h long, comprising 2 h for acclimation and the following 4 h for oxygen measurement. As a result of weight dissimilarity between specimens, OCRs were later standardized to 10 g animals, assuming a scaling coefficient of -0.20 (see [Clarke and Johnston, 1999](#)).

Thermal sensitivity (*Q*₁₀) was determined for the temperature intervals 18–26, 18–30 and 26–30°C, using the standard equation:

$$Q_{10} = \left(\frac{R_2}{R_1} \right)^{10/(T_2 - T_1)},$$

where *R*₁ and *R*₂ represent the OCRs at temperatures *T*₁ and *T*₂, respectively.

Ventilation rates were measured by counting the number of opercular beats per minute. This procedure was repeated five times per individual (over 5 consecutive days), immediately before feeding to exclude any potential bias caused by feeding on respiration.

Feed intake and behavioural patterns

Seahorses were fed 100 frozen enriched adult *Artemia* twice a day. Feed intake was determined by collecting and counting the leftovers at the end of the day. Feed intake was later size corrected based on a daily feed intake of 5% of the body weight, in order to set aside size differences in this variable.

Seahorse behaviour was monitored through direct observation by blinded observers. In previous behavioural studies with this species (e.g. [Faleiro *et al.*, 2008](#); [Aur lio *et al.*, 2013](#)), we were able to see that seahorses did not change normal behavioural patterns during passive and careful observation. Behavioural analysis was performed based on the ethogram described in [Table 1](#) (adapted from [Faleiro *et al.*, 2008](#)). The time spent performing each activity was measured for each seahorse during 15 min per day and was later converted to a percentage of total time. This procedure was repeated five times per individual (over 5 consecutive days), comprising a total of 75 min of observation per seahorse and 450 min per treatment. Behavioural observations were made in the morning, 30 min after feeding.

Statistical analysis

ANOVA was used to test for significant differences between sexes and seahorses from different systems of the same treatment. Given that no significant differences were found between them, all data from the same treatment were pooled and analysed together. The effects of the different temperature and pH scenarios on the OCRs, ventilation rates, feed intake and behavioural patterns of adult seahorses (*n* = 6)

Table 1: Ethogram of *Hippocampus guttatus* activity patterns (adapted from [Faleiro *et al.*, 2008](#))

Category	Behaviour	Description
Rest	Inactive	The seahorse remains resting, without performing any kind of movement, while attached or unattached to the holdfast
	Swinging	The seahorse remains attached to the holdfast, with slight movements of the head or body
Activity	Feeding	The seahorse tilts the body in search for food, points the snout towards the prey and swallows it
	Swimming	The seahorse swims, actively moving the dorsal and pectoral fins

were then evaluated using two-way ANOVAs, followed by Tukey's *post hoc* tests. All statistical analyses were performed for a significance level of 0.05, using Statistica 10.0 software.

Results

Metabolic rates, thermal sensitivity and ventilation rates

Ocean warming and acidification had a significant impact on the metabolism of *H. guttulatus* (Fig. 1 and Supplementary Table S2). The OCR of adult seahorses increased significantly with temperature in both normocapnic ($P < 0.001$) and hypercapnic conditions ($P < 0.001$). The future warming scenario promoted an increase in OCR from 3.97 ± 0.38 (at 26°C) to $5.47 \pm 1.03 \mu\text{mol O}_2 \text{ g}^{-1} \text{ h}^{-1}$ (at 30°C) during normocapnia and from 3.74 ± 0.19 (at 26°C) to $4.99 \pm 0.00 \mu\text{mol O}_2 \text{ g}^{-1} \text{ h}^{-1}$ (at 30°C) in acidified conditions. Thermal sensitivity varied between 1.25 and 2.22 depending on the climate scenario.

Ventilation rates of adult seahorses were also significantly affected by temperature ($P < 0.001$) and its interaction with pH ($P = 0.001$; Fig. 2 and Supplementary Table S2). During normocapnia, the ventilation rates followed the trend of metabolic rates, increasing with warming from 41.6 ± 18.3 (at 26°C) to $59.7 \pm 16.2 \text{ beats min}^{-1}$ (at 30°C). In the acidified scenario, however, the ventilation rates did not keep up with the increase in OCR, decreasing with warming from 49.2 ± 12.5 (at 26°C) to $40.2 \pm 3.6 \text{ beats min}^{-1}$ (at 30°C).

Feed intake and behavioural patterns

The feed intake of adult seahorses did not increase with warming ($P = 0.895$), but was significantly affected by pH ($P < 0.001$; Fig. 3 and Supplementary Table S2). In acidified conditions, seahorse feeding was inhibited, which promoted a decrease in prey consumption from 27–30 to 7–10 prey h^{-1} .

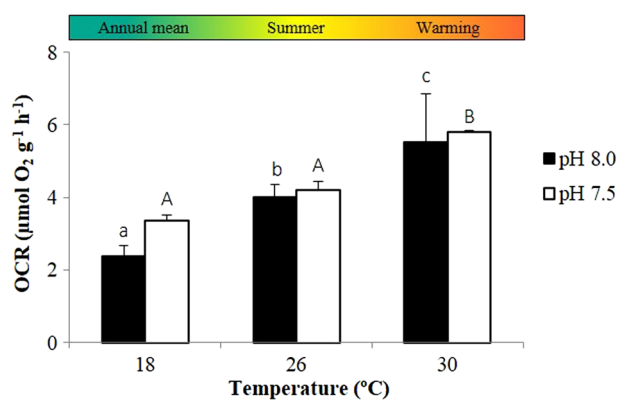

Figure 1: Impact of ocean warming and acidification on the oxygen consumption rates (OCRs) of adult seahorses, *H. guttulatus*, in resting conditions. Values are shown as means + SD ($n = 6$). Different lower case letters represent significant differences ($P < 0.05$) between temperatures at pH 8.0 and different upper case letters represent significant differences ($P < 0.05$) between temperatures at pH 7.5.

Figure 2: Impact of ocean warming and acidification on the ventilation rates of adult seahorses, *H. guttulatus*. Values are shown as means + SD ($n = 6$). Different lower case letters represent significant differences ($P < 0.05$) between temperatures at pH 8.0 and different upper case letters represent significant differences ($P < 0.05$) between temperatures at pH 7.5.

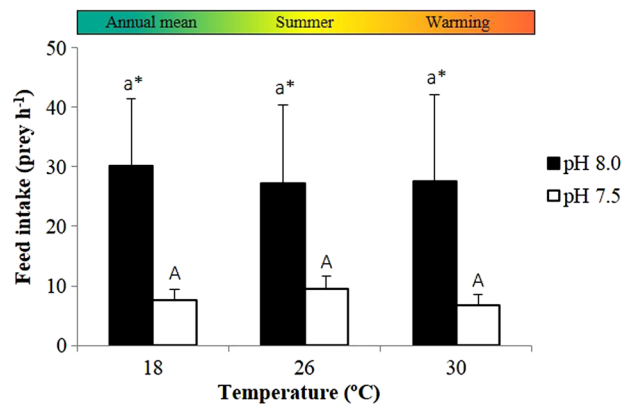

Figure 3: Impact of ocean warming and acidification on the feed intake of adult seahorses, *H. guttulatus*. Values are shown as means + SD ($n = 6$). Different letters and asterisks represent significant differences ($P < 0.05$) between temperature and pH conditions, respectively. Lower case letters are used for differences between temperatures at pH 8.0 and upper case letters for differences between temperatures at pH 7.5.

Additionally, the seahorses in acidified conditions spent less time feeding than those in normocapnic conditions ($P < 0.001$; Fig. 4 and Supplementary Table S2).

In a similar way, seahorse behaviour remained almost unchanged with warming, but was influenced by pH (Fig. 4 and Supplementary Table S2). In hypercapnic conditions, seahorses spent less time in activity and more time resting ($P < 0.001$).

Discussion

Phenotypic responses to climate change are already taking place in today's oceans; for instance, many animals are migrating polewards to more environmentally suitable areas (Perry

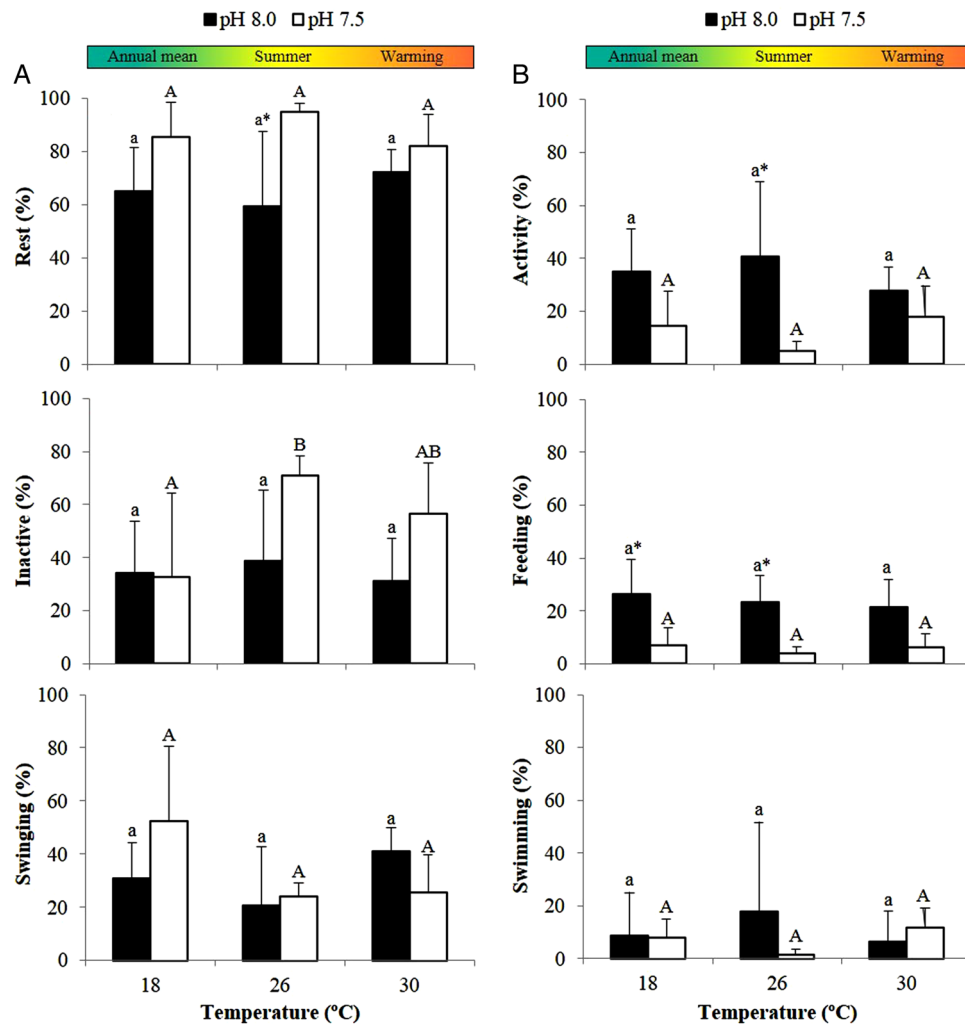

Figure 4: Impact of ocean warming and acidification on the behavioural patterns of adult seahorses, *H. guttulatus*. (A) Rest, which includes 'inactive' and 'swinging' behaviours. (B) Activity, which includes 'feeding' and 'swimming' behaviours. Values are shown as means + SD ($n = 6$). Different letters and asterisks represent significant differences ($P < 0.05$) between temperature and pH conditions, respectively. Lower case letters are used for differences between temperatures at pH 8.0 and upper case letters for differences between temperatures at pH 7.5.

et al., 2005). Seahorses may not, however, benefit much from this strategy, because these poor swimmers are sparsely distributed in structurally complex habitats and rely on camouflage to survive. Moreover, migration is also expected to have profound impacts on their reproductive success, because it increases the chances of losing a mate. Seahorses establish faithful pair bonds that allow them to increase their reproductive efficiency and to avoid the risks of searching for a new mate. When pair bonds are broken, seahorses may have trouble finding a new partner due to reduced mate availability; even when partners are replaced, the reproductive output may be affected (Foster and Vincent, 2004). Thus, given these constraints, seahorses may have to rely more heavily than other fishes on their physiological ability to cope with predicted climate changes. In this study, we show that, even though adult seahorses may be relatively well prepared to face future

changes in ocean temperature, they may not be able to cope with the combined effects of warming and acidification, which are predicted to act synergistically in the future ocean.

As expected for ectothermic animals, seahorse metabolism increased under the near-future warming scenario. Nonetheless, the increase in metabolic rates resulted in normal values of thermal sensitivity (Q_{10} values around 2), which suggests that adult seahorses were not under severe thermal stress. Indeed, seahorse behaviour remained reasonably unaffected by higher temperatures. The great thermal tolerance of *H. guttulatus* is not entirely unexpected, because these eurythermic animals are commonly found in shallow inshore waters, mainly in estuarial inlets and coastal lagoons (Lourie *et al.*, 2004), where they endure significant daily and seasonal temperature fluctuations. Their physiological ability to tolerate large temperature

oscillations may thus give them a chance to face future increases in ocean temperature.

Although adult seahorses have shown great resilience to higher temperatures (see also Aurélio *et al.*, 2013), we cannot exclude potential negative impacts of long-term warming. In fact, in the present study there were some signs that seahorses may not be totally indifferent to higher temperatures. For instance, feeding rates did not follow the increase in metabolic rates with warming as expected. Whether similar feeding rates at higher temperatures will be enough to satisfy the greater energetic demands at these temperatures or if they will have a further negative impact on fish performance and welfare over a long-term perspective remains unclear. Long-term effects on vital biological features (such as survival, growth and reproduction) should be addressed further, in order to uncover potentially hidden impacts of ocean warming on adult seahorses.

In the present study, ocean acidification had a more pronounced impact on seahorses than warming. In conditions of lower pH, ventilation rates declined with rising temperature, feeding rates decreased considerably, and the activity levels were also reduced. This lethargic response may indicate that seahorses were struggling against a stress element. Indeed, as hypercapnia is known to enhance gill ventilation of fishes (Ishimatsu *et al.*, 2004), the decreased ventilation rates of seahorses in warming and acidified conditions may indicate acid-base imbalance. The consequences of this lethargic state during hypercapnia to long-term seahorse welfare remain unclear, but may ultimately affect growth rates and reproductive potential.

Fishes have evolved efficient ion-regulatory mechanisms that allow them to compensate pH rapidly and maintain their internal ionic environment through the exchange of ions across the gills (Pörtner *et al.*, 2004; Perry and Gilmour, 2006). Nonetheless, exposure to elevated CO₂ has been shown to have detrimental effects on several aspects of fish life, including behaviour (e.g. Jutfelt *et al.*, 2013), growth and survival (e.g. Baumann *et al.*, 2011), skeletal and otolith development (e.g. Munday *et al.*, 2011), cardiovascular function (e.g. Ishimatsu *et al.*, 2004) and respiratory physiology (e.g. Munday *et al.*, 2009), even though most effects have been observed in fingerlings.

The combined effects of ocean warming and acidification had a negative impact on the behaviour and physiology of adult *H. guttulatus* seahorses. Moreover, their effects on early stages are expected to be much more severe, because newborns proved to be much more sensitive to warming than adult seahorses, evidencing signs of metabolic suppression when exposed to temperatures higher than 28°C (Aurélio *et al.*, 2013). Even though the effects of climate change on other seahorse species are still unknown, ocean warming and acidification may represent, in the near future, an extra threat to seahorse conservation. Seahorses already face several challenges in the wild (including habitat degradation and overexploitation), and climate change may increase their vulnerability further. Fortunately, given the time frame in which ocean warming and acidification are expected to occur, there is still an opportunity for adaptation.
